Metview - Macro Language

Iain Russell, Sándor Kertész, Fernando li Meteorological Visualisation Section, ECMWF

 Designed to perform data manipulation and plotting from within the Metview environment

```

                            q = gradientb(q)
```

Uses of Macro Language

- Generate visualisation plots directly
- Generate a derived data set to drop in plot or animation windows or to input to other applications
- Provide a user interface for complex tasks
- Incorporate macros in scheduled tasks thus use Metview in an operational environment, run in batch mode

Data For Tutorial

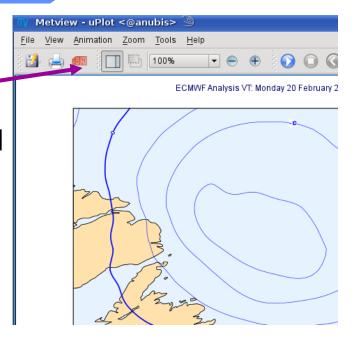

- cd ~/metview
- -trx/mv_data/get_macro_data
- Data is unzipped into
 - metview/macro_tutorial

Creating a Macro Program

- Save visualisation as Macro limited in scope
- Drop icons inside Macro Editor, add extra bits
- Write from scratch (the more macros you write, the more you recycle those you have done, lessening the effort)

The Macro Editor

[New to Metview 4]

```

                                                                             L: 13, C: 1
```

The Macro Editor

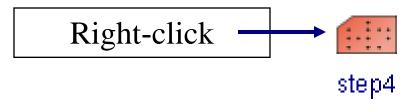

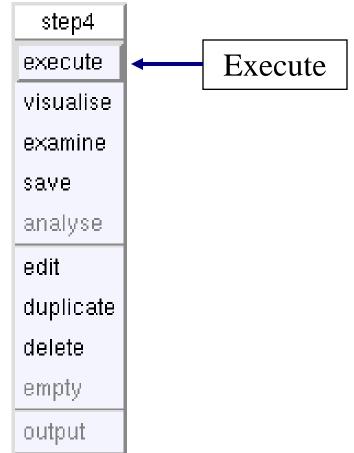

- [New to Metview 4]
- Drop icons directly into the editor
- Run (automatically saves the macro first)
- Tab settings (Settings | Tabs...)
- Insert function name (F2)
- Insert code template (F4)
- Advanced run options

Executing Macros Another Way

Macro Documentation

- For now, the Metview 3 documentation plus the Metview 4 updates page, newsletter articles and tutorials
- http://www.ecmwf.int/publications/manuals/metview
 - → documentation.html
 - → change_history.html
 - → training/index.html
- 'Full' Metview 4 documentation is in progress

Tutorial Steps 1-4

- Steps 1-4: Basic intro input, basic contours, plot window, variables and functions
- Steps 5-7 : Outputs other than on-screen
- Step 8 : Macro run mode control
- Steps 9-10 : User Interfaces in Macro
- Step 11 : Macro in Batch
- Steps 12a,b,c : Using functions in Macro (libraries)
- Embedding FORTRAN and C in Macro

Macro Essentials - Variables

- No need for declaration
- Dynamic typing

```
a = 1  # type(a) = 'number'
a = 'hello' # type(a) = 'string'
a = [4, 5] # type(a) = 'list'
a = |7, 8| # type(a) = 'vector'
```

Macro Essentials - Strings

'Hello' is the same as "Hello"

 Concatenate strings with strings, numbers and dates using the '&' operator

```
eg. "part1_" & "part2_" & 3
produces "part1_part2_3"
```

Obtain substrings with substring()

```
e.g. substring ("Metview", 2, 4)

produces "etv"

first last
```

Macro Essentials - Strings

- Split a string into parts using parse()
- Creates a list of substrings

```
n = parse("z500.grib", ".")
print ("name = ", n[1], " extension = ", n[2])
```

prints the following string:

name = z500 extension = grib

- Dates defined as a built-in type year, month, day, hour, minute and second.
- Dates can be created as literals using :
 - yyyy-mm-dd
 - yyyy-DDD
 - where: yr, yyyy 4 digit yr, mm 2 digit month, dd 2 digit day, DDD - 3 digit Julian day.
- The time can be added using :
 - ♦ HH:MM or HH:MM:SS

Function date() creates dates from numbers:

```
d1 = date(20080129)
today = date(0)
yesterday = date(-1)
```

- Hour, minute and second components are zero.
- To create a full date, use decimal dates:

```
d = date(20080129.5)
or
d = 2008-01-29 + 0.5
or
d = 2008-01-29 + hour(12)
```

 Note that numbers passed to Metview modules are automatically converted to dates:

```
r = retrieve(date : -1, ...)
r = retrieve(date : 20070101, ...)
```

Loops on dates using a for loop:

```
for d = 2007-01-01 to 2007-03-01 do
end for
for d = 2007-01-01 to 2007-03-01 by 2 do
end for
for d = 2007-01-01 to 2007-03-01 by hour(6) do
     print(d)
end for
```

 Ordered, heterogeneous collection of values. Not limited in length. List elements can be of any type, including lists.
 List are built using square brackets, and can be initialised with nil:

```
l = [3,4,"foo","bar"]

l = nil

l = 1 & [2,3,[3,4]]

l = 1 & ["str1"] & ["str2"]

europe = [35,-12.5,75,42.5] # S, W, N, E
```

- Accessing List Elements
- Indexes start at 1

```
mylist = [10,20,30,40]
a = mylist[1]  # a = 10
b = mylist[2,4]  # b = [20,30,40] (m to n)
c = mylist[1,4,2] # c = [10,30] (step 2)
```

Useful List Functions

```
num_elements = count (mylist)
sorted = sort (mylist)
  # can provide custom sorting function
  if (2 in mylist) then
   ...
end if
```

Useful List Functions [New to Metview 4]

```
mylist = ['b', 'a', 'a', 'c']
```

```
# find occurrences of 'a' in list
index = find(mylist, 'a') # 2
indexes = find(mylist, 'a', 'all') # [2,3]
# return list of unique members
reduced = unique(mylist) # ['b', 'a', 'c']
```

- List Operations [New to Metview 4]
- Operators acting on lists will act on each list element, returning a list of results
- a = [3, 4]
 b = a + 5 # b is now [8, 9]
 c = a * b # c is now [24, 36]

 Lists are general-purpose, and are not recommended for handling large numbers (thousands) of numbers – for that, use vectors (see later)

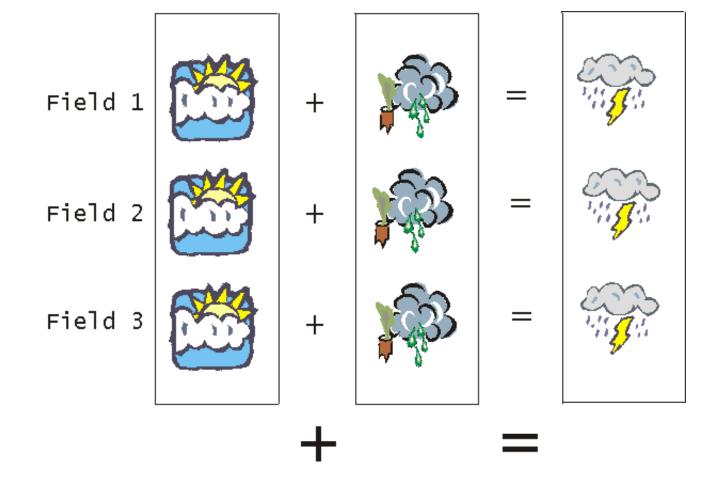

Definition

- ♦ Entity composed of several meteorological fields, (e.g. output of a MARS retrieval).
- Operations and functions on fieldsets
 - Operations on two fieldsets are carried out between each pair of corresponding values within each pair of corresponding fields. The result is a new fieldset.

```
result = fieldset_1 + fieldset_2
```

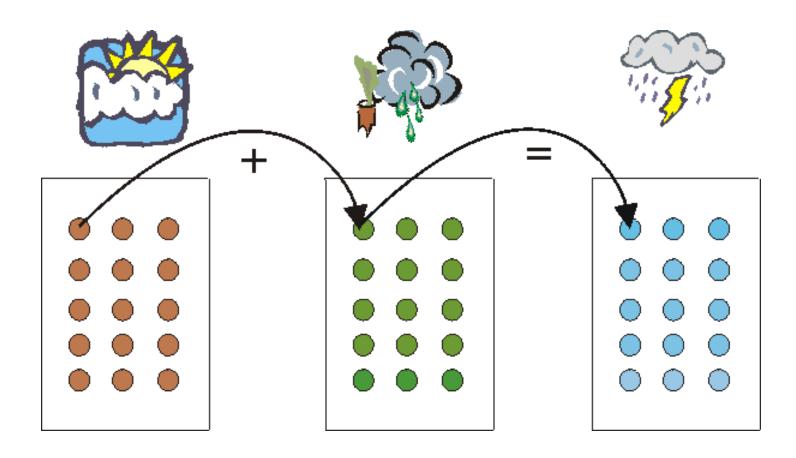

- Operations and functions on fieldsets
 - Can also combine fieldsets with scalars:

$$Z = X - 273.15$$

Gives a fieldset where all values are 273.15 less than the original (Kelvin to Celcius)

Functions such as log:

$$Z = log(X)$$

- Operations and functions on fieldsets
 - ♦ Boolean operators such as > or <= produce, for each point, 0 when the comparison fails, or 1 if it succeeds:</p>

$$Z = X > 0$$

Gives a fieldset where all values are either 1 or 0

- can be used as a mask to multiply by
- bitmap() can be used to invalidate values

e.g.

```
t2m_masked = t2m * landseamask
t2m masked = bitmap (t2m masked, 0)
```

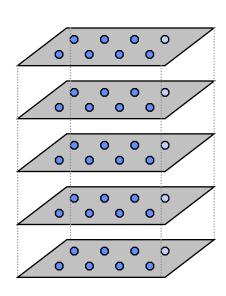

suppose that fieldset 'fs' contains 5 fields:

- accumulate(fs)
 - → returns a list of 5 numbers, each is the sum of all the values in that field
- \$ sum(fs)
 - → returns a single field where each value is the sum of the 5 corresponding values in the input fields

```
→ e.g. mean(), maxvalue(), stdev(), coslat()
```

Building up fieldsets

- fieldset & fieldset , fieldset & nil
- merge several fieldsets. The output is a fieldset with as many fields as the sum of all fieldsets.

```
fs = nil
for d = 2006-01-01 to 2006-12-31 do
    x = retrieve(date : d, ...)
    fs = fs & x
end for
```

♦ This is useful to build a fieldset from nothing.

Extracting fields from fieldsets

- → fieldset [number]
- fieldset [number,number]
- fieldset [number,number,number]

Examples:

```
y = x[2] # copies field 2 of x into y

y = x[3,8] # copies fields 3,4,5,6,7 and 8

y = x[1,20,4] # copies fields 1, 5, 9, 13 and 17
```

- Writing Fieldsets as Text
 - **♦** Easy to save in Geopoints format (see next slide)

```
for i = 1 to count (fields) do
    gpt = grib_to_geo (data : fields[i])
    write ('field_' & i & '.gpt', gpt)
end for
```

Tutorial Steps 5-7

- Steps 1-4: Basic intro input, basic contours, plot window, variables and functions
- Steps 5-7 : Outputs other than on-screen
- Step 8 : Macro run mode control
- Steps 9-10 : User Interfaces in Macro
- Step 11 : Macro in Batch
- Steps 12a,b,c : Using functions in Macro (libraries)
- Embedding FORTRAN and C in Macro

Macro Essentials - Loops, Tests & Functions

- The for, while, repeat, loop statements
 - ♦ See 'Metview Macro Syntax' handout

- The if/else, when, case statements
 - ♦ See 'Metview Macro Syntax' handout

- Function declarations
 - ♦ See 'Metview Macro Syntax' handout

Macro Essentials - Functions

Multiple versions

♦ Can declare multiple functions with the same name, but with different parameter number/types.

```
function fn_test ()
function fn_test (param1: string)
function fn_test (param1: number)
```

Correct one will be chosen according to the supplied parameters

Tutorial Step 8

- Steps 1-4: Basic intro input, basic contours, plot window, variables and functions
- Steps 5-7 : Outputs other than on-screen
- Step 8 : Macro run mode control
- Steps 9-10 : User Interfaces in Macro
- Step 11 : Macro in Batch
- Steps 12a,b,c : Using functions in Macro (libraries)
- Embedding FORTRAN and C in Macro

Tutorial Steps 9-10

- Steps 1-4: Basic intro input, basic contours, plot window, variables and functions
- Steps 5-7 : Outputs other than on-screen
- Step 8 : Macro run mode control
- Steps 9-10 : User Interfaces in Macro
- Step 11 : Macro in Batch
- Steps 12a,b,c : Using functions in Macro (libraries)
- Embedding FORTRAN and C in Macro

Tutorial Step 11

- Steps 1-4: Basic intro input, basic contours, plot window, variables and functions
- Steps 5-7 : Outputs other than on-screen
- Step 8 : Macro run mode control
- Steps 9-10 : User Interfaces in Macro
- Step 11 : Macro in Batch
- Steps 12a,b,c : Using functions in Macro (libraries)
- Embedding FORTRAN and C in Macro

Tutorial Step 12

- Steps 1-4: Basic intro input, basic contours, plot window, variables and functions
- Steps 5-7 : Outputs other than on-screen
- Step 8 : Macro run mode control
- Steps 9-10 : User Interfaces in Macro
- Step 11 : Macro in Batch
- Steps 12a,b,c : Using functions in Macro (libraries)
- Embedding FORTRAN and C in Macro

Fortran and C in Macro - Introduction

 Users can write their own Macro functions in Fortran or C/C++, extending the Macro language

 Used in tasks which cannot be achieved by macro functions. Or use existing FORTRAN/C code to save time.

 FORTRAN/C-Metview macro interfaces support input data of types GRIB, number, string and vector. BUFR, images and matrices are waiting implementation.

Fortran and C in Macro - Introduction

3 interfaces available:

- ♦ Macro/Fortran Interface (MFI)
 - → Uses GRIB_API for fieldsets (GRIB 1 and 2)
- ♦ Macro/C Interface (MCI)
 - → Uses GRIB_API for fieldsets (GRIB 1 and 2)
- **♦ Legacy Macro/Fortran interface**
 - → Uses GRIBEX for fieldsets (GRIB 1 only)
 - → May disappear in the future

Fortran/C in Macro - General Approach my

- Embed FORTRAN/C source code in the macro source file
 - ♦ Metview will automatically compile it at run-time
- OR
- Compile FORTRAN/C program separately or take an existing executable

- FORTRAN/C program is treated as another macro function
- E.g. specify some MARS retrievals to provide input fieldsets, use FORTRAN/C function to provide derived field(s);

Fortran/C in Macro - Inline Code

 Embed the FORTRAN/C code in the macro program using the inline keyword

Fortran/C in Macro - External Binary

 OR specify location of the FORTRAN/C executable to the macro program

```
basic (modified) - /home/graphics/cgi/metview/macro_tutorial_prep/

                                                     Help
hics/cgi/metview/macro_tutorial_prep/for_overheads/basic 1181 bytes | L: 55 | C: 27
extern gradientb(f:fieldset) "gradientb"
# Retrieve the specific humidity
q = retrieve(
          date
          param : "q",
level : 700,
                          [1.5, 1.5]
          grid
 Compute the gradient of Q
q = gradientb(q)
```

Fortran/C in Macro - General Approach my

 Use suite of FORTRAN/C routines to get the input arguments, obtain GRIB_API handles for interrogation of GRIB data, save and set results, - these are the "interface routines" (mfi_*, mci_*).

- Schematically, the FORTRAN/C program dealing with a GRIB file is composed of
 - a section where input is read and output prepared
 - a loop where fields are loaded, expanded, validated, processed and saved
 - ♦ a section where output is set

Fortran in Macro - A Simple Example

- Advection of scalar field requires FORTRAN/C program to obtain the gradient of the field.
- Assume you will have a FORTRAN program called gradientb returning the gradient of a fieldset in two components (then advection is trivial). First concentrate on the writing of the macro program itself.
- Examine macro provided, which computes advection of specific humidity q at 700 hPa
- Examine FORTRAN source code provided, which computes gradient of a field

Fortran in Macro - A Simple Example

- Note interface routines, prefixed by "MFI" (e.g.
 - mfi_get_fieldset, mfi_load_one_grib, mfi_save_grib). Most of the FORTRAN code is standard to process a GRIB fieldset.
- User routine GRAD() calculates gradient of input fieldset in two components:
 - saved separately and coded as wind components -
 - each can be accessed separately in the macro for the calculation of the advection.
- Two methods for making the program visible to macros:

Method 1: write the FORTRAN code inline – i.e., inside the macro code itself:

```
extern gradientb(f:fieldset) "fortran90" inline
PROGRAM GRADIENTB

CALL mfi_get_fieldset(fieldset_in, icount)

. . .
end inline
```

- This can be written directly into the macro that will use it or else in a separate file.
- If written to a separate file, it can be accessed with the include macro command.
- If named correctly, it can be placed in the Macro folder of the System folder (~uid/metview/System/Macros). In this case, the calling macro does not need any extra lines in order to use this function.

- Method 2: compile and link the FORTRAN program separately. Then:
- a) inform the macro program where to find the FORTRAN executable:

```
extern gradientb(f:fieldset)
  "/home/xy/xyz/metview/fortran/gradientb"
```

- or b) place the executable in the Macro folder of the System folder (~uid/metview/System/Macros)
 - ♦ No need to specify this location to the macro

- Finally, save the macro and execute to obtain the desired result.
- The procedure above is fairly general and with minor changes, can be adapted to other tasks just by replacing the processing routine.
- NOTE: in some cases, it may be a good idea to perform the GRIB handling within Macro, extract the values and coordinates as *vectors*, and pass these to the inline FORTRAN/C code instead – simpler inline code.

- Scope and Visibility
 - Variables inside functions are local
- Functions cannot see 'outside' variables

```
x = 9  # cannot see y here
function func
    y = 10  # cannot see x here
end func
    # cannot see y here
```

Scope and Visibility

... unless a variable is defined to be 'global'

```
global g1 = 9  # cannot see y1 here
function func
    y1 = 10 + g1  # can see g1 here
end func
    # cannot see y1 here
```

Scope and Visibility

- ... a better solution is to pass a parameter
- ... that way, the function can be reused in other macros

```
x = 9
func(x)  # x is passed as a parameter
function func (t : number) #t adopts value of x
  y1 = 10 + t  # y1 = 10 + 9
end func
```

- Destroying variables automatically
 - ♦ When they go out of scope

```
function plot_a
  a = retrieve(...)
  plot(a)
end plot_a
# Main routine
plot_a() # a is created and destroyed
```

- Destroying variables manually
 - ♦ Set to zero

```
a = retrieve(...)
plot(a) # we have finished with 'a' now
a = 0
b = retrieve(...)
plot(b)
```

- Hold spatially irregular data
- ASCII format file

```
#GEO

```

- Operations on geopoints
 - Generally create a new set of geopoints, where each value is the result of the operation on the corresponding input value

- \$\int \text{geo_new} = \text{geo_pts} + 1
 - → Means "add 1 to each geopoint value, creating a new set of geopoints".

Operations on geopoints

- \$\int \text{geo_gt_5} = \text{geo_pts} > 5
 - → Means "create a new set of geopoints of 1 where input value is greater than 5, and 0 where it is not".

Filtering geopoints

- result = filter (geo_pts, geo_pts > 5)
- result = filter (geo_pts, geo_gt_5)

Equivalent

- → Means "extract from the first set of geopoints the points where the corresponding point in the second parameter is non-zero".
- → Means "create a new set of geopoints consisting only of those points whose value is greater than 5".

```
geo_pts : (3, 4, 5, 6, 7, 8)
```

$$geo_gt_5$$
: (0, 0, 0, 1, 1, 1)

result : (6, 7, 8)

- Example of functions on geopoints
 - count (geopoints)
 - → Returns the number of points

- distance (geopoints, number, number)
 - → Returns the set of distances from the given location
- mean (geopoints)
 - → Returns the mean value of all the points

- Combining Fieldsets And Point Data
 - Point data is stored in geopoints variables
 - Combination of geopoints and fieldsets is done automatically by Metview Macro :
 - → for each geopoint, find the corresponding value in the fieldset by interpolation
 - now combine corresponding values (add, subtract etc.)
 - → the result is a new geopoints variable
 - only considers the first field in a fieldset

Macro Essentials - ASCII Tables [MV4] my

- ASCII Tables columns of data in text files
 - ♦ E.g. CSV (Comma Separated Value)
 - Various parsing options for different formats
- Metview can directly visualise these, or read columns of data into vectors (numeric) or lists of strings (text)
- Metview can currently only read ASCII Tables, not write

```
Station, Lat, Lon, T2m
1,71.1,28.23,271.3
2,70.93,-8.67,274.7
```

Macro Essentials - Vectors [MV4]

 Ordered, array of numbers. Much more efficient than lists for high volumes of numeric data. Vectors are built using the vertical bar symbol, and can be initialised with nil:

$$v = |7, 8, 9|$$

```
v = nil # start from nil and append
v = v & |4.4, 5.5, 3.14| & |8, 9|
```

```
v = vector(10000) # pre-allocate space
v[1] = 4 # assign values to indexes
```

Assigning/replacing a range of values at once:

$$v = |10,20,30,40|$$

 $v[2] = |99,99| # v is now |10,99,99,40|$

Operations and functions are applied to each element:

- Accessing vector elements
- Indexes start at 1

```
v = |10,20,30,40|
a = v[1]   # a = 10
b = v[2,4]   # b = |20,30,40| (m to n)
c = v[1,4,2]   # c = |10,30| (step 2)
d = v[1,4,2,2]   # d = |10,20,30,40|
   # (take 2 at each step)
```

 The raw data in most file formats supported by Metview can be extracted into a vector:

```
vals = values(fieldset)
vals = values(netcdf)
vals = values(geopoints)
vals = values(table, 'column_A')
vals = values(odb, 'column_A')
```

- Vectors honour missing values and will not include them in calculations
- For computations with many steps, vectors can be the most efficient way to do it
- Stored in memory, no intermediate files on disk (but greater memory usage!)
- Operations on lists of vectors:

```
a = [v1,v2] * [v3,v4]
# a is now [v1*v3, v2*v4]
```

- A collection of named items (members)
- Eg

Icon-functions take definitions:

```
acoast = mcoast(
     map_coastline_resolution
                                          "high",
     map coastline colour
                                          "red",
     map grid colour
                                          "grey",
     map_grid_longitude_increment
                                          10,
     map label colour
                                          "grey",
     map coastline land shade
                                          "on",
     map_coastline_land_shade_colour:
                                          "cream"
```

```
param def = ( param : "Z",
              type : "FC",
             date : -1,
              step : 24 )
# retrieve as LL grid or not according to user
# choice
if (use_LL = "yes") then
 param_def.grid = [1.5, 1.5]
end if
Z_ret = retrieve (param_def)
```

```
common_input = ( levtype : "PL",
                 levelist: 850,
                 time : 12,
                 grid: [2.5,2.5],
                 type: "AN" )
Uan = retrieve ( common input,
                 date : -1,
                 param : "U" )
Van = retrieve ( common_input,
                 date : -2,
                 param : "V" )
```

Macro Essentials - Data Input

- For GRIB files, read() reads the data into a fieldset
- For BUFR files, read() reads the data into an observations variable (usually convert to geopoints before using)
- For geopoints, read() reads the data into a geopoints variable
- For netCDF, read() reads the data into a netcdf variable
- For ODB, read() reads the data into an odb variable (Observational DataBase – see separate tutorial on the web)

Macro Essentials - Data Input

- For ASCII tables, read_table() reads the data into a table variable
- For other ASCII data, read() reads the data into a list, where each element is a string containing a line of the text file. Use string functions parse() and substring() to separate elements further.

Macro Essentials - Data Output

- Use the write() function
 - using filename, subsequent calls overwrite
 - using file handler, subsequent calls append
- Can also use append()
- Automatic file format

fieldset -> GRIB file

observations -> BUFR file

geopoints -> geopoints file

netcdf -> netcdf file

string -> ASCII file (custom formats)

Macro Documentation

- For now, the Metview 3 documentation plus the Metview 4 updates page, newsletter articles and tutorials
- http://www.ecmwf.int/publications/manuals/metview
 - documentation.html
 - change_history.html
 - → training/index.html
 - → Material from this course will soon appear there!
