## 4D Variational Data Assimilation

4D-Var comprises the minimisation of:

$$J(\mathbf{x}) = \frac{1}{2}[\mathcal{H}(\mathbf{x}) - \mathbf{y}]^T \mathbf{R}^{-1}[\mathcal{H}(\mathbf{x}) - \mathbf{y}] \\ + \frac{1}{2}(\mathbf{x}_0 - \mathbf{x}_b)^T \mathbf{B}^{-1}(\mathbf{x}_0 - \mathbf{x}_b) + \frac{1}{2}\mathcal{F}(\mathbf{x})^T \mathbf{C}^{-1}\mathcal{F}(\mathbf{x})$$

- $\mathbf{x}$  is the 4D state of the atmosphere over the assimilation window.
- $\mathcal{H}$  is a 4D observation operator, accounting for the time dimension.
- $\mathcal{F}$  represents the remaining theoretical knowledge after background information has been accounted for (balance, DFI...).
- Control variable reduces to  $\mathbf{x}_0$  using the hypothesis:  $\mathbf{x}_i = \mathcal{M}_i(\mathbf{x}_{i-1})$ .
- The solution is a trajectory of the model  $\mathcal{M}$  even though it is not perfect...

- A typical assumption in data assimilation is to ignore model error (bias and random).
- The perfect model assumption limits the length of the analysis window that can be used to roughly 12 hours.
- Model bias can affect assimilation of some observations (radiance data in the stratosphere).
- In **weak constraint 4D-Var**, we define the **model error** as

$$\eta_i = \mathbf{x}_i^t - \mathcal{M}_i(\mathbf{x}_{i-1}^t) \quad \text{for } i = 1, \dots, n$$

and we allow it to be non-zero.

- Note:  $\mathbf{x}^t$  represents the true atmospheric state which is of course not known.

## Weak Constraint 4D-Var

- We can derive the weak constraint cost function using Bayes' rule:

$$p(\mathbf{x}_0 \cdots \mathbf{x}_n | \mathbf{x}_b; \mathbf{y}_0 \cdots \mathbf{y}_n) = \frac{p(\mathbf{x}_b; \mathbf{y}_0 \cdots \mathbf{y}_n | \mathbf{x}_0 \cdots \mathbf{x}_n) p(\mathbf{x}_0 \cdots \mathbf{x}_n)}{p(\mathbf{x}_b; \mathbf{y}_0 \cdots \mathbf{y}_n)}$$

- The denominator is independent of  $\mathbf{x}_0 \cdots \mathbf{x}_n$ .
- The term  $p(\mathbf{x}_b; \mathbf{y}_0 \cdots \mathbf{y}_n | \mathbf{x}_0 \cdots \mathbf{x}_n)$  simplifies to:

$$p(\mathbf{x}_b | \mathbf{x}_0) \prod_{i=0}^n p(\mathbf{y}_i | \mathbf{x}_i)$$

- Hence

$$p(\mathbf{x}_0 \cdots \mathbf{x}_n | \mathbf{x}_b; \mathbf{y}_0 \cdots \mathbf{y}_n) \propto p(\mathbf{x}_b | \mathbf{x}_0) \left[ \prod_{i=0}^n p(\mathbf{y}_i | \mathbf{x}_i) \right] p(\mathbf{x}_0 \cdots \mathbf{x}_n)$$

$$p(\mathbf{x}_0 \cdots \mathbf{x}_n | \mathbf{x}_b; \mathbf{y}_0 \cdots \mathbf{y}_n) \propto p(\mathbf{x}_b | \mathbf{x}_0) \left[ \prod_{i=0}^n p(\mathbf{y}_i | \mathbf{x}_i) \right] p(\mathbf{x}_0 \cdots \mathbf{x}_n)$$

- Taking minus the logarithm gives the cost function:

$$J(\mathbf{x}_0 \cdots \mathbf{x}_n) = -\log p(\mathbf{x}_b | \mathbf{x}_0) - \sum_{i=0}^n \log p(\mathbf{y}_i | \mathbf{x}_i) - \log p(\mathbf{x}_0 \cdots \mathbf{x}_n)$$

- The terms involving  $\mathbf{x}_b$  and  $\mathbf{y}_i$  are the background and observation terms of the strong constraint cost function.
- The final term is new. It represents the *a priori* probability of the sequence of states  $\mathbf{x}_0 \cdots \mathbf{x}_n$ .

## Weak Constraint 4D-Var

- Given the sequence of states  $\mathbf{x}_0 \cdots \mathbf{x}_n$ , we can calculate the corresponding model errors:

$$\eta_i = \mathbf{x}_i - \mathcal{M}_i(\mathbf{x}_{i-1}) \quad \text{for } i = 1, \dots, n$$

- We can use our knowledge of the statistics of model error to define

$$p(\mathbf{x}_0 \cdots \mathbf{x}_n) \equiv p(\mathbf{x}_0; \eta_1 \cdots \eta_n)$$

- One possibility is to assume that model error is uncorrelated in time. In this case:

$$p(\mathbf{x}_0 \cdots \mathbf{x}_n) \equiv p(\mathbf{x}_0)p(\eta_1) \cdots p(\eta_n)$$

- If we take  $p(\mathbf{x}_0) = \text{const.}$  (all states equally likely), and  $p(\eta_i)$  as Gaussian with covariance matrix  $\mathbf{Q}_i$ , weak constraint 4D-Var adds the following term to the cost function:

$$\frac{1}{2} \sum_{i=1}^n \eta_i^T \mathbf{Q}_i^{-1} \eta_i$$

## Weak Constraint 4D-Var

- For Gaussian, temporally-uncorrelated model error, the weak constraint 4D-Var cost function is:

$$\begin{aligned}
 J(\mathbf{x}) &= \frac{1}{2}(\mathbf{x}_0 - \mathbf{x}_b)^T \mathbf{B}^{-1}(\mathbf{x}_0 - \mathbf{x}_b) \\
 &+ \frac{1}{2} \sum_{i=0}^n [\mathcal{H}_i(\mathbf{x}_i) - \mathbf{y}_i]^T \mathbf{R}_i^{-1} [\mathcal{H}_i(\mathbf{x}_i) - \mathbf{y}_i] \\
 &+ \frac{1}{2} \sum_{i=1}^n [\mathbf{x}_i - \mathcal{M}_i(\mathbf{x}_{i-1})]^T \mathbf{Q}_i^{-1} [\mathbf{x}_i - \mathcal{M}_i(\mathbf{x}_{i-1})]
 \end{aligned}$$

- Do not reduce the control variable using the model and retain the 4D nature of the control variable.
- Account for the fact that the model contains some information but is not exact by adding a model error term to the cost function.
- The model  $\mathcal{M}$  is not verified exactly: it is a weak constraint.
- If model error is correlated in time, the model error term contains additional cross-correlation blocks.

## 4D-Var with Model Error Forcing

$$J(\mathbf{x}_0, \eta) = \frac{1}{2} \sum_{i=0}^n [\mathcal{H}(\mathbf{x}_i) - \mathbf{y}_i]^T \mathbf{R}_i^{-1} [\mathcal{H}(\mathbf{x}_i) - \mathbf{y}_i] \\ + \frac{1}{2} (\mathbf{x}_0 - \mathbf{x}_b)^T \mathbf{B}^{-1} (\mathbf{x}_0 - \mathbf{x}_b) + \frac{1}{2} \eta^T \mathbf{Q}^{-1} \eta$$

with  $\mathbf{x}_i = \mathcal{M}_i(\mathbf{x}_{i-1}) + \eta_i$ .

- $\eta_i$  has the dimension of a 3D state,
- $\eta_i$  represents the instantaneous model error,
- $\eta_i$  is propagated by the model.
- All results shown later are for constant forcing over the length of one assimilation window, i.e. for correlated model error.

## 4D-Var with Model Error Forcing

- TL and AD models can be used with little modification,
- Information is propagated between observations and initial condition control variable by TL and AD models.

  - Systematic Model Error
  - Is it model error?
- 6 Towards a long assimilation window
- 7 Summary and Discussion

## 4D State Control Variable

- Use  $\mathbf{x} = \{\mathbf{x}_i\}_{i=0,\dots,n}$  as the control variable.
- Nonlinear cost function:

$$\begin{aligned} J(\mathbf{x}) &= \frac{1}{2}(\mathbf{x}_0 - \mathbf{x}_b)^T \mathbf{B}^{-1}(\mathbf{x}_0 - \mathbf{x}_b) \\ &+ \frac{1}{2} \sum_{i=0}^n [\mathcal{H}(\mathbf{x}_i) - \mathbf{y}_i]^T \mathbf{R}_i^{-1} [\mathcal{H}(\mathbf{x}_i) - \mathbf{y}_i] \\ &+ \frac{1}{2} \sum_{i=1}^n [\mathcal{M}(\mathbf{x}_{i-1}) - \mathbf{x}_i]^T \mathbf{Q}_i^{-1} [\mathcal{M}(\mathbf{x}_{i-1}) - \mathbf{x}_i] \end{aligned}$$

- In principle, the model is not needed to compute the  $J_o$  term.
- In practice, the control variable will be defined at regular intervals in the assimilation window and the model used to fill the gaps.

## 4D State Control Variable

- Model integrations within each time-step (or sub-window) are independent:
  - Information is not propagated across sub-windows by TL/AD models,
  - Natural parallel implementation.
- Tangent linear and adjoint models:
  - Can be used without modification,
  - Propagate information between observations and control variable within each sub-window.
- Several 4D-Var cycles are coupled and optimised together.

## Model Error Covariance Matrix

- An easy choice is  $\mathbf{Q} = \alpha\mathbf{B}$ .
- If  $\mathbf{Q}$  and  $\mathbf{B}$  are proportional,  $\delta\mathbf{x}_0$  and  $\eta$  are constrained in the same directions, may be with different relative amplitudes.
- They both predominantly retrieve the same information.
  
- $\mathbf{B}$  can be estimated from an ensemble of 4D-Var assimilations.
- Considering the forecasts run from the 4D-Var members:
  - At a given step, each model state is supposed to represent the same *true* atmospheric state,
  - The tendencies from each of these model states should represent possible evolutions of the atmosphere from that same *true* atmospheric state,
  - The differences between these tendencies can be interpreted as possible uncertainties in the model or realisations of *model error*.
- $\mathbf{Q}$  can be estimated by applying the statistical model used for  $\mathbf{B}$  to tendencies instead of analysis increments.
- $\mathbf{Q}$  has narrower correlations and smaller amplitudes than  $\mathbf{B}$ .

## Model Error Covariance Matrix

- Most of the techniques developed to model **B** can be re-used to model **Q** (spectral technique, wavelets, filtering...).
- Obtaining samples of model error is much more difficult:
  - Currently, tendency differences between integrations of the members of an ensemble are used as a proxy for samples of model error.
  - Use results from stochastic representation of uncertainties in EPS.
  - Compare the covariances of  $\eta$  produced by the current system with the matrix **Q** being used.
- It is possible to derive an estimate of  $\mathbf{HQH}^T$  from cross-covariances between observation departures produced from pairs of analyses with different length windows (R. Todling).
  - This produces a projection of **Q** on a fixed observing network, not in the full matrix.
- Characterising the statistical properties of model error is one of the main current problems in data assimilation and ensemble forecasting.

## Weak Constraint 4D-Var with Cycling Term

- Model error is not only random: there are biases.
- For random model error, the 4D-Var cost function is:

$$\begin{aligned}
 J(\mathbf{x}_0, \eta) &= \frac{1}{2} \sum_{i=0}^n [\mathcal{H}(\mathbf{x}_i) - \mathbf{y}_i]^T \mathbf{R}_i^{-1} [\mathcal{H}(\mathbf{x}_i) - \mathbf{y}_i] \\
 &\quad + \frac{1}{2} (\mathbf{x}_0 - \mathbf{x}_b)^T \mathbf{B}^{-1} (\mathbf{x}_0 - \mathbf{x}_b) + \frac{1}{2} \eta^T \mathbf{Q}^{-1} \eta
 \end{aligned}$$

- For systematic model error, we might consider:

$$\begin{aligned}
 J(\mathbf{x}_0, \eta) &= \frac{1}{2} \sum_{i=0}^n [\mathcal{H}(\mathbf{x}_i) - \mathbf{y}_i]^T \mathbf{R}_i^{-1} [\mathcal{H}(\mathbf{x}_i) - \mathbf{y}_i] \\
 &\quad + \frac{1}{2} (\mathbf{x}_0 - \mathbf{x}_b)^T \mathbf{B}^{-1} (\mathbf{x}_0 - \mathbf{x}_b) + \frac{1}{2} (\eta - \eta_b)^T \mathbf{Q}^{-1} (\eta - \eta_b)
 \end{aligned}$$

- Test case: can we address the model bias in the stratosphere?

Temperature, Model Level 60

Min = -0.07, Max = 0.06, RMS Global=0.00, N.hem=0.01, S.hem=0.00, Tropics=0.00

- The only significant source of observations in the box is aircraft data (Denver airport).
- Removing aircraft data in the box eliminates the spurious forcing.

Observations are biased.

Figure from Lars Isaksen

## Is it model error?

## Strong Constraint

## Weak Constraint

The mean temperature increment is smaller with weak constraint 4D-Var (Stratosphere only, June 1993).

## Is it model error?

ERA interim

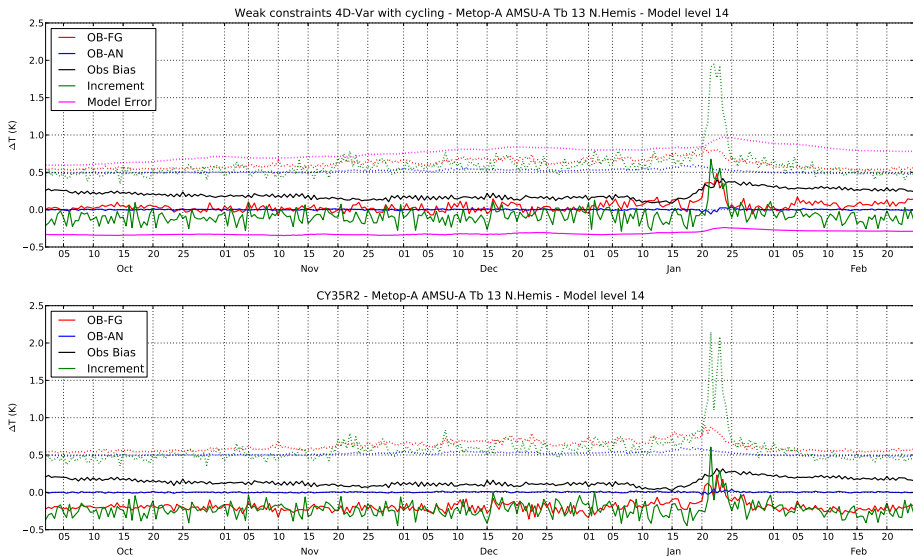

Weak Constraint

The work on model error has helped identify other sources of error in the system (balance term).

## Observation Error or Model Error?

Observation error bias correction can compensate for model error.

# Weak Constraint 4D-Var Configurations

- 6-hour sub-windows:

- Better than 6-hour 4D-Var: two cycles are coupled through  $J_q$ ,
  - Better than 12-hour 4D-Var: more information (imperfect model), more control.
- Single time-step sub-windows:
  - Each assimilation problem is instantaneous = 3D-Var,
  - Equivalent to a string of 3D-Var problems coupled together and solved as a single minimisation problem,
  - Approximation can be extended to non instantaneous sub-windows.

## Weak Constraint 4D-Var: Summary and Questions

- In the forcing formulation of weak constraint 4D-Var:
  - Background term to address systematic error,
  - Interactions with variational observation bias correction,
  - Extend model error to the troposphere and to other variables (humidity).
- Weak constraint 4D-Var with a 4D state control variable:
  - Four dimensional problem with a coupling term between sub-windows and can be interpreted as a smoother over assimilation cycles.
  - Can we extend the incremental formulation?
- The two weak constraint 4D-Var approaches are mathematically equivalent (for linear problems) but lead to very different minimization problems.
  - Can we combine the benefits of treating sub-windows in parallel with efficient minimization?
  - 4D-Var scales well up to 1,000s of processors, can it scale to 100,000s of processors in the future?

## Weak Constraint 4D-Var: Open Questions

- Weak Constraint 4D-Var allows the perfect model assumption to be removed and the use of longer assimilation windows.
  - How much benefit can we expect from long window 4D-Var?
- Weak Constraint 4D-Var requires knowledge of the statistical properties of model error (covariance matrix).
  - The forecast model is such an important component of the data assimilation system. It is surprising how little we know about its error characteristics.
  - How can we access realistic samples of model error? How can observations be used?
  - 4D-Var can handle time-correlated model error. What type of correlation model should be used?
  - Can we distinguish model error from observation bias or other errors? Is there a need to anchor the system?
- The statistical description of model error is one of the main current challenges in data assimilation.
